

12. Addendum

English Translation Draft — boundary cases, additional observations, and comparative notes

One-line summary: Organizes boundary cases, additional observations, experimental logs, and comparative tests that could not be fully covered in the main text.

This chapter records boundary cases, additional observations, exceptional behavior, experimental logs, comparative tests, and supplementary considerations that could not be fully integrated into the main chapters.

Some entries are based on limited trial counts or differing observation conditions. Accordingly, this addendum separates confirmed specifications, observed tendencies, hypotheses, and reference cases. Its purpose is not to assert internal specifications, but to preserve observation records for later testing and comparative research.

12-1. Gold Bracelet Tests

One-line summary: The Gold Bracelet tests recorded boundary behavior that was difficult to explain through uniform selection alone, including candidate-count increases and Performance-Source Contamination.

The Gold Bracelet was treated as a relatively unusual observation target when organizing candidate structure and inheritance behavior. Multiple boundary-oriented tests examined candidate-count increases, Performance-Source Contamination, order destabilization, candidate competition, and fixed-leaning behavior.

Some tests showed little behavioral change despite an increased candidate count, comparatively persistent candidates, or less competition than expected. These cases are retained as observations, not as proof of a mechanism. Trial count, condition control, and the number of comparison cases remain limited.

Results may also vary with candidate-pool size, arrangement structure, source-equipment composition, and the state of Performance-Source Contamination.

12-2. Diamond Brooch Observations

One-line summary: Organizes how mixed-category candidates and Messhilite participation may affect target-composition probability, together with a combinatorial approximation.

Tests with the Diamond Brooch examined candidate mixing, mixed-category composition, pool-size increases, and possible candidate compression in accessory inheritance.

Observed success tendencies could change substantially depending on whether added materials were of the same type, of different types, or included Messhilite. Same-type additions

could improve the number of successful combinations for a single-target composition, while mixed-category additions could dilute relevant candidates and reduce the probability of the intended composition.

Intuitive sequential-order reasoning did not always align with the combination-based probability. The approximation below therefore ignores draw order and counts combinations that satisfy the three target slots.

m	N	Target	Example candidate structure	Successful combinations	All combinations	Approx. success	Expected trials
0	4	G/L/S	[G][L][S][M]	1	4	25%	4
1	5	G/L/S	[G][L][S][M] +[G]	2	10	20%	5
2	6	G/L/S	[G][L][S][M] +[G][G]	3	20	15%	6.67
3	7	G/L/S	[G][L][S][M] +[G][G][G]	4	35	11.43%	8.75

Boundary note: G = Glitter Augite, L = Love Crystal, S = Singing Crystal, M = Messhilite. Internal draw order, weighting, and priority remain unknown; this is a combination-count approximation, not an internal-process model.

12-3. Candidate-Count Boundary Tests

One-line summary: Summarizes observed differences around $N \leq 3$ and $N \geq 4$ in fixed-leaning behavior, order destabilization, candidate competition, and practical workload.

Within the observed range, $N \leq 3$ more often produced fixed-leaning behavior. At $N \geq 4$, order destabilization and candidate competition tended to increase, sometimes raising practical reroll difficulty sharply.

This boundary may vary with candidate category, Performance-Source Contamination state, arrangement structure, and Auto-Arrange participation. The document therefore does not claim that $N=3$ is completely fixed or that $N=4$ always collapses. It records only that the vicinity of $N=3$ may function as a practical boundary.

Item	Around $N \leq 3$	Around $N \geq 4$
Fixed-leaning behavior	Comparatively common	More likely to break down
Order destabilization	Less frequent tendency	More frequent tendency
Candidate competition	Comparatively limited	More likely to increase
Unwanted candidates	Comparatively suppressed	More likely to appear

Practical difficulty	Comparatively stable	Can rise sharply
Save-splitting importance	Moderate	High
Reroll workload	Comparatively light	More likely to increase
Sense of fixation	Stronger	More likely to weaken
Evidence state	Some repeatable tendency	Boundary variation observed

12-4. Order-Destabilization Observations

One-line summary: Records candidate-order variation associated with larger pools, mixed candidates, Performance-Source Contamination, and Auto-Arrange, while leaving internal priority and processing order unresolved.

Additional tests examined displayed candidate order and inheritance order. Candidate-count increases, mixed-category candidates, Performance-Source Contamination, and Auto-Arrange were associated with greater order variation in the observed cases.

Some apparently identical conditions still produced different orders, candidate count alone did not explain every case, and fixed-leaning behavior coexisted with order destabilization. The evidence does not support classifying the process as either fully fixed or fully random. Internal priority or internal processing-order effects remain possible but unverified.

12-5. AI Coordination Comparison

One-line summary: Compares observed coordination tendencies in ChatGPT, Copilot, and Gemini without treating the table as a ranking of overall AI capability.

Experimental equipment-coordination generation and comparison were conducted with ChatGPT, Copilot, and Gemini. Differences sometimes appeared in worldbuilding interpretation, roleplay emphasis, performance emphasis, color consistency, and explanation style.

Common tendencies included attention to initial equipment, setting consistency, character identity, and separation of novelty-oriented builds from practical builds. Full logs and detailed analysis are outside the scope of this equipment-inheritance document.

AI	Worldbuilding	Performance	Structural organization	Roleplay tendency
ChatGPT	○	○	⊙	○
Copilot	○	△	○	△
Gemini	⊙	△	○	⊙
AI	Comparatively prominent tendency	Observed characteristic		

ChatGPT	Structure and condition organization	Often separates conditions and organizes configurations
Copilot	Alternative viewpoints and supplementary organization	Often supplies different interpretations or supporting perspectives
Gemini	Worldbuilding and atmosphere	Often expands roleplay and setting interpretation

12-6. Additional Verification Notes

One-line summary: Lists partially organized observations and future tests that were not fully integrated into the main document.

Unorganized notes remain for candidate-count boundaries, order fixation, Performance-Source Contamination, recursive inheritance, Auto-Arrange participation, and cross-series comparisons. The list below preserves their current evidence state and next verification route.

This repository is not a final, complete specification analysis. It is also an observation record, hypothesis map, practical guide, and work-in-progress research archive. Future observations may require reorganization or reinterpretation.

Topic	Current state	Main observation	Next verification
Candidate-count boundary	Partly organized	Fixed-leaning tendency around N=3	Compare condition differences
Order destabilization	Ongoing observation	Greater variation as candidate count rises	Large-sample comparison
Performance-Source Contamination	Observed	High-frequency participation in some equipment	Identify internal conditions
Recursive inheritance	Hypothesis stage	Possible preservation across multiple generations	Test depth limit
Candidate compression	Hypothesis stage	Some behavior does not match apparent candidate count	Compare possible internal priority
Series differences	Insufficient comparison	Possible RF4/RF5 differences	Cross-title comparison

Terminology lineage note: The Japanese source uses the former terms 自己混入 / 自己性能混入. This English edition applies the Current terminology Performance-Source Contamination; the former wording is retained here only for source-lineage traceability.

Current-difference note — recursive processing: The table above preserves Canonical 12 as a historical snapshot, where recursive inheritance was classified as “Hypothesis stage.” Current Repository document 05 records observation-based support for internal reference at depth 1 and possible re-reference during subsequent inheritance. Depth 2 and beyond, the recursion limit, and the internal algorithm remain unresolved. This note does not upgrade those Unknowns or rewrite the historical table.
